Field of the Invention The present invention relates to an apparatus for forming a lead frame adapted to be employed in packaging semiconductor elements, etc. 2. Description of the Related Art Japanese Patent Laid-Open No. H11-346727 discloses a method for molding a ceramic lead frame to be employed in packaging semiconductor elements, as will be described later. The ceramic lead frame is produced by the steps of: preparing a lead frame having a concave portion formed at the center thereof, said lead frame being made of Ni or an Ni alloy; pressing said concave portion with a forming mold, thereby molding the frame with an organic resin; and setting a ceramic mold to be used for firing in said concave portion, thereby firing said lead frame. The organic resin is often formed by using thermosetting resin. In this method, there is a possibility of inducing swelling of the thermosetting resin during heating during the molding, and of causing a problem of crack formation in the ceramic mold at the time of firing. It is not possible to completely eliminate the possibility of occurrence of such problems because the thermosetting resin is utilized. Further, since the organic resin is heated at a high temperature at the time of firing, the organic resin itself has a risk of increasing the possibility of swelling. Furthermore, the lead frame is molded by pressing the concave portion of the lead frame with a mold. The pressing causes warpage of the lead frame. In addition, after pressing, it is often the case that the resin leaks from the conc

Q: OOP and Memory Management? I was recently talking with my friend, and he brought up the concept of memory management in regards to class instances. He asked why we should pay to use a class instance, since the memory can simply be allocated using the heap. It seems to me that using the 'new' operator does a better job at managing memory allocation, and that using it is a lot more efficient. My question is, why use class instances over just using the heap. We all know that the heap is part of the program space, and is finite, whereas the actual program space is unlimited. For all intents and purposes, a class instance should be as powerful as a reference to a variable in the heap. The reason I'm asking this is because it seems that C++ does a much better job of managing memory than C# does, so I'm trying to learn more about what C++ is really doing.

A: My question is, why use class instances over just using the heap. We all know that the heap is part of the program space, and is finite, whereas the actual program space is unlimited. The memory that an instance of a class occupies is not all that large. If you make a class that stores a lot of data, it might be a lot bigger than the total of the size of all the data in it. But you can create objects of that class and not notice. It's the same reason that it is possible to have 2 GB of RAM and not notice any performance problems when the program runs. We all know that the heap is part of the program space, and is finite. Yes, but the program space is not finite. In fact, it has no limit. It is infinitely large. Therefore, there is no limit to how much data you can store in it.

A: The key difference is that the main memory is a shared resource, so the kernel has to give it out to the processes to use. The memory for an object will be allocated from the private virtual address space of each process - not just those of the running process. That means the object can't be shared between processes, but it can
